

**Eigensystems**

*Eigenvectors, Orthogonal Matrices, Eigenvector Decomposition, Rank*

**Eigenvector equation**

- Eigen-systems help us to understand mappings
- A vector  $v$  is said to be an **eigenvector** if

$$Mv = \lambda v$$

- $M$  is square (i.e.  $n \times n$ )
- Where the number  $\lambda$  is the **eigenvalue**
- Eigenvalues play a fundamental role in understanding operators

**Proof of Orthogonality**

- $(Mv_i = \lambda_i v_i)^T$  implies  $v_i^T M^T = \lambda_i v_i^T$
- When  $M$  is symmetric then  $Mv_i = \lambda_i v_i \Rightarrow v_i^T M = \lambda_i v_i^T$
- Consider two eigenvectors  $v_i$  and  $v_j$  of  $M$

$$\begin{aligned} v_i^T M v_j &= (v_i^T M) v_j = \lambda_i v_i^T v_j \\ &= v_i^T (M v_j) = \lambda_j v_i^T v_j \end{aligned}$$

- So either  $\lambda_i = \lambda_j$  or  $v_i^T v_j = 0$
- If  $\lambda_i = \lambda_j$  then any linear combination of  $v_i$  and  $v_j$  is an eigenvector ( $M(av_i + bv_j) = \lambda_i(av_i + bv_j)$ ). So I can choose two eigenvectors that are orthogonal to each other.

**Orthogonal Matrices**

- We can construct an **orthogonal** matrix  $V$  from the eigenvectors

$$V = (v_1, v_2, \dots, v_n)$$

- Matrix  $V$  is an  $n \times n$  matrix
- Because of the orthogonality of the vectors  $v_i$

$$V^T V = \begin{pmatrix} v_1^T v_1 & v_1^T v_2 & \dots & v_1^T v_n \\ v_2^T v_1 & v_2^T v_2 & \dots & v_2^T v_n \\ \vdots & \vdots & \ddots & \vdots \\ v_n^T v_1 & v_n^T v_2 & \dots & v_n^T v_n \end{pmatrix} = \begin{pmatrix} 1 & 0 & \dots & 0 \\ 0 & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1 \end{pmatrix} = I$$

- Eigenvectors**
- Orthogonal Matrices**
- Eigen Decomposition**
- Low Rank Approximation**

**Symmetric Matrices**

- If  $M$  is an  $n \times n$  **symmetric** matrix then it has  $n$  real orthogonal eigenvectors with real eigenvalues
- We denote the  $i^{th}$  eigenvector by  $v_i$  and the corresponding eigenvalue by  $\lambda_i$  so that

$$Mv_i = \lambda_i v_i$$

- Orthogonal means that if  $i \neq j$  then

$$v_i^T v_j = 0$$

- (We can always normalise eigenvectors if we want)

**Outline**

- Eigenvectors**
- Orthogonal Matrices**
- Eigen Decomposition**
- Low Rank Approximation**

**The Other Way Around**

- We have shown that  $V^T V = I$
- Thus multiply both sides on the left by  $V$

$$V V^T V = V I$$

- $V$  will have an inverse,  $V^{-1}$ , such that  $V V^{-1} = I$
- Multiplying the equation on the right by  $V^{-1}$

$$\begin{aligned} (V V^T) V V^{-1} &= V V^{-1} I \\ V V^T &= I \end{aligned}$$

- Note that,  $V^{-1} = V^T$  (definition of orthogonal matrix)

## Invertible Matrices

- A matrix,  $M$ , will be singular (uninvertible) if there exists a vector  $x \neq 0$  such that

$$Mx = 0$$

- Now if there exists such a vector such that  $Vx = 0$  then multiply by  $V^T$  we get

$$V^T Vx = V^T 0$$

$$x = 0$$

since  $V^T V = I$

- Thus  $V$  is invertible

## Rotations

- Orthogonal matrices satisfy  $V^T V = V V^T = I$
- As a consequent they define rotations (and possibly a reflection)

- Consider a vector  $x$  and  $x' = Vx$ , now

$$\|x'\|_2^2 = x'^T x' = (Vx)^T (Vx) = x^T V^T V x = x^T x = \|x\|_2^2$$

- Similarly if additionally  $y' = Vy$  then

$$\langle x', y' \rangle = (Vx)^T (Vy) = x^T V^T V y = x^T y = \langle x, y \rangle = \|x\|_2 \|y\|_2 \cos(\theta)$$

- Rotations and reflections preserve lengths and angles

## Outline

- Eigenvectors
- Orthogonal Matrices
- Eigen Decomposition
- Low Rank Approximation

## Matrix Decomposition

- Taking the matrix of eigenvectors,  $V$ , then

$$MV = M(v_1, v_2, \dots, v_n) = (\lambda_1 v_1, \lambda_2 v_2, \dots, \lambda_n v_n) = V\Lambda$$

- where  $\Lambda = \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_n) = \begin{pmatrix} \lambda_1 & 0 & \dots & 0 \\ 0 & \lambda_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \lambda_n \end{pmatrix}$

- Now

$$M = MVV^T = V\Lambda V^T$$

- Very important *similarity transform*

## Mappings by Symmetric Matrices

$$M = \begin{pmatrix} 0.83 & -0.31 \\ -0.31 & 1.9 \end{pmatrix} = V\Lambda V^T = \begin{pmatrix} \cos(-75^\circ) & \sin(-75^\circ) \\ -\sin(-75^\circ) & \cos(-75^\circ) \end{pmatrix} \begin{pmatrix} 2 & 0 \\ 0 & 0.75 \end{pmatrix} \begin{pmatrix} \cos(75^\circ) & \sin(75^\circ) \\ -\sin(75^\circ) & \cos(75^\circ) \end{pmatrix}$$

## Inverses

- For any symmetric invertible matrix

$$M = V\Lambda V^T \quad M^{-1} = V\Lambda^{-1} V^T$$

- Where  $\Lambda^{-1} = \text{diag}(\frac{1}{\lambda_1}, \frac{1}{\lambda_2}, \dots, \frac{1}{\lambda_n}) = \begin{pmatrix} \frac{1}{\lambda_1} & 0 & \dots & 0 \\ 0 & \frac{1}{\lambda_2} & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \frac{1}{\lambda_n} \end{pmatrix}$

- Since

$$MM^{-1} = (V\Lambda V^T)(V\Lambda^{-1} V^T) = V\Lambda(V^T V)\Lambda^{-1} V^T = V\Lambda\Lambda^{-1} V^T = VV^T = I$$

- I.e, Small eigenvalues become large eigenvalues and visa verse

## III-Conditioning Again

## Condition Number

- Taking matrix inverses can be inherently unstable
- Any small error can be amplified by taking the inverse
- The stability of the inverse depends on the ratio of smallest eigenvalue to the largest eigenvalue (i.e. the biggest possible amplification compared to the smallest)
- For invertible matrices we can take the largest eigenvalue as a norm of the matrix
- The condition number is given by

$$\|M\|_H \times \|M^{-1}\|_H = \frac{|\lambda_{\max}|}{|\lambda_{\min}|}$$

- Large condition number implies very ill-conditioned

1. Eigenvectors
2. Orthogonal Matrices
3. Eigen Decomposition
4. **Low Rank Approximation**

## “Inverting” Rank Deficient Matrices

- Rank deficient matrices are non-invertible (i.e. we don't know the vector  $x$  such that  $Mx = b$ ) as we don't know the component of the  $x$  in the null space
- Although we don't know  $x$  we can find a vector,  $x$ , that satisfies  $Mx = b$
- Given a symmetric  $n \times n$  matrix with  $k$  non-zero eigenvalues  $\lambda_1, \lambda_2, \dots, \lambda_k$  we can construct a “pseudo inverse”  $M^+$  as  $V\Lambda^+V^T$  where  $\Lambda^+ = \text{diag}(\frac{1}{\lambda_1}, \frac{1}{\lambda_2}, \dots, \frac{1}{\lambda_k}, 0, \dots, 0)$
- This finds the vector  $x$  with no component in the null space (it is the solution with the smallest norm)
- This is a different to the pseudo inverse for non-square matrices

## Summary

- Linear mappings are commonly used in machine learning algorithms such as regression
- We can understand symmetric operators by looking at their eigenvectors
- Any symmetric matrix can be decomposed as  $M = V\Lambda V^T$ 
  - ★ where  $V$  are orthogonal matrices whose rows are the eigenvector
  - ★ and  $\Lambda$  is a diagonal matrix of the eigenvalues
- This decomposition allows us to understand inverse mappings

- The rank of a matrix,  $M$ , is the number of non-zero eigenvalues
- The space spanned by the eigenvectors  $v_a, v_b$ , etc. with zero eigenvalue forms a **null space**
- Any vector in the null space will get projected to the zero vector

$$M(av_a + bv_b + \dots) = 0$$

- A square matrix is said to be **rank deficient** if it has any eigenvectors with eigenvalue equal to 0
- This happens when the columns of the matrix are not linearly independent

## Low Rank Approximation

- Recall that matrices with large and small eigenvectors are ill-conditions so the inverse has the potential to greatly amplify any measurement error
- One work around is to set all small eigenvalues to zero and use the pseudo inverse
- Setting small eigenvalues to zero reduces the rank of the matrix and is an example of a low rank approximation
- Low rank approximations are much used to obtain approximate models for arrays of data (we will revisit this when we look at SVD)
