Removing Variance By Averaging

- We can reduce the variance and hence improve our generalisation error by averaging over different learning machines
- There are a number of different techniques for doing this that go by the name of ensemble methods or ensemble learning!
- This trick can be used with many different learning machines, but is clearly most practical for machine that can be trained quickly!
- (nevertheless, even for deep learning taking the average response of many machines is usually done to win competitions)

Decision Trees

- A decision trees builds a binary tree to partition the data, $\mathcal{D} = \{(x_i, y_i) | i = 1, ..., m\}$, into the leaves of the treel
- Each decision rule depends on a single feature
- At each step the rule is chosen that maximise the "purity" of the leaf nodes
- Decisions can be made on numerical values or categories

Leaf Purity

- Two different purity measures, $Q_m(\mathcal{L})$, for a leaf node \mathcal{L} are commonly used
 - * Gini index

$$Q_m^g(\mathcal{L}) = \sum_{c \in \mathcal{C}} p_c(\mathcal{L}) \left(1 - p_c(\mathcal{L})\right) \mathbf{I}$$

Cross-entropy

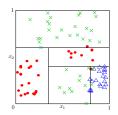

$$Q_m^e(\mathcal{L}) = -\sum_{c \in \mathcal{C}} p_c(\mathcal{L}) \log(p_c(\mathcal{L})) \mathbf{I}$$

Ensembling of Decision Trees

- One set of algorithms where ensembling are common place are decision trees
- These are particularly good for handling messy data
 - ⋆ categorical data
 - ★ mixture of data types
 - ★ missing data
 - ⋆ large data sets
 - ⋆ multiclass
- In many competitions ensembled trees, particularly random forests and gradient boosting beat all other techniques

Partitioning

- \bullet Consider a classification problems with examples (x,y) belonging to some classes $y \in \mathcal{C} \mathbf{I}$
- The data is partitioned by the tree into leaves

 \bullet The proportion of data points in leaf ${\mathcal L}$ belonging to class c is

$$p_c(\mathcal{L}) = \frac{1}{|\mathcal{L}|} \sum_{(\boldsymbol{x}, y) \in \mathcal{L}} [\![y = c]\!]$$

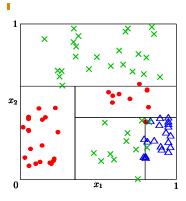

where $[\![y=c]\!]=1$ if y=c and 0 otherwise

Building Decision Trees

Observations Outline

• Decision trees are very useful for exploring new data sets-the tree shows what features are most important

- Decision trees can also be used for regression problems
 - * Approximate function by a series of rules
 - * Reduce variance between data points assigned to leaf nodes
- CART is a classic implementation that builds Classification And Regression Trees
- Decision trees depend strongly on the early decisions and so vary a lot for slightly different data sets-high variance

Error In The Means

• By taking the mean over many samples we can reduce the

variance and thus improve our generalisation performance

• To get a feel for this consider estimating the mean of a random variable, X, from a number of samples (n=5 in the example

below)

 $f_X(x)$

Adam Prügel-Bennet

 $\mu = \mathbb{E}[X]$ $\sigma^2 = \mathbb{E}[(X - \mu)^2]$

1. Decision Trees

2. Bagging

Mean and Variance

• The expected value of the mean, $\hat{\mu}_n$, of n random **independent** variables, X_i , is the expected value $\mu = \mathbb{E}[X_i]$

$$\mathbb{E}[\hat{\mu}_n] = \mathbb{E}\left[\frac{1}{n}\sum_{i=1}^n X_i\right] = \frac{1}{n}\sum_{i=1}^n \mathbb{E}[X_i] = \frac{1}{n}\sum_{i=1}^n \mu = \mu \mathbb{I}$$

• The variance is $\mathbb{E} \left[(\hat{\mu}_n - \mu)^2 \right]$ or equivalently

$$\begin{split} \frac{1}{n^2} \mathbb{E} \left[\left(\sum_{i=1}^n (X_i - \mu) \right)^2 \right] &= \frac{1}{n^2} \mathbb{E} \left[\sum_{i=1}^n (X_i - \mu)^2 + \sum_{i=1}^n \sum_{\substack{j=1 \ j \neq i}}^n (X_i - \mu)(X_j - \mu) \right] \right] \\ &= \frac{1}{n^2} \sum_{i=1}^n \left(\mathbb{E} \left[(X_i - \mu)^2 \right] + \sum_{\substack{j=1 \ j \neq i}}^n \mathbb{E} \left[X_i - \mu \right] \mathbb{E} \left[X_j - \mu \right] \right) \\ &= \frac{1}{n^2} \sum_{i=1}^n \sigma^2 \mathbb{I} = \frac{1}{n} \sigma^2 \mathbb{I} \end{split}$$

Bootstrap Aggregation (Bagging)

• To reduce the variance in a learning machine (such as a decision tree) we can average over many machines

- To average many machines they must learn something different
- We only have one data set, but we can resample from the data set to make them look a bit different—this is known a **bootstrapping**

 $(\boldsymbol{x}_5,\,y_5)\ (\boldsymbol{x}_4,\,y_4)\ (\boldsymbol{x}_5,\,y_5)\ (\boldsymbol{x}_6,\,y_6)\ (\boldsymbol{x}_2,\,y_2)\ (\boldsymbol{x}_1,\,y_1)$ (x_1, y_1) (x_5, y_5) (x_3, y_3) (x_2, y_2) (x_5, y_5) (x_2, y_2) (x_4, y_4) (x_3, y_3) (x_1, y_1) (x_6, y_6) (x_4, y_4) (x_6, y_6) (x_2, y_2) (x_3, y_3) (x_4, y_4) (x_6, y_6) (x_2, y_2)

Performance of Bagging

- Bootstrapping is an early form of data augmentation
- For classification we get our different machines to vote
- For regression we can average the prediction of different machines
- Bagging improves the performance of decision trees
- However, we can usually do better using Boosting
- This is because our decision trees are correlated

Variance of Positive Correlated Variables

• If we calculate the variance of the mean of positively correlated variables with correlation ρ we find

$$\frac{1}{n^2} \mathbb{E}\left[\left(\sum_{i=1}^n X_i - \mu\right)^2\right] = \rho \sigma^2 + \frac{1-\rho}{n} \sigma^2$$

$$(\rho = \mathbb{E}[(X_i - \mu)(X_j - \mu)]/\sigma^2)$$

- \bullet As $n\to\infty$ the second term vanishes, but we are left with the first
- If we want to do well we need our learning machines to be unbiased and decorrelated

Random Forest

- In random forests we average much less correlated trees
- ullet To do this for each tree we choose a subset of $p'\ll p$ of the features on which to split the tree
- Typically p' can range from 1 to \sqrt{p}
- The trees aren't that good, but are very decorrelated
- By averaging over a huge number of trees (order of 1000) we typically get good results
- Random Forest won (wins?) many competitions

https://tinyurl.com/bddhrhcw

https://tinyurl.com/bddhrhcw

Lessons

- \bullet Ensemble methods have proved themselves to be very powerful
- They work by averaging over different machines, trying to reduce their variance
- Here the variance comes from forcing the machines to learn different functions using Bootstrap Aggregation
- Tend to work best with very simple models (true of random forest and boosting)

 —seems to reduce over-fitting

 ■
- Random forest is very powerful, but gradient boosting is competitive
