Gaussian Processes

Gaussian Processes, regression

Outline

- 1. Introduction
- 2. Gaussian Processes
- 3. Bayesian Inference
- 4. Hyper-parameters

- Gaussian processes (GPs) are a mathematically defined ensemble of functions
- They can be combined with Bayesian inference to give one of the most powerful regression techniques
- Although Bayesian they can be used in a black-box fashion due to the ubiquity of the prior
- Mathematically they are a bit complicated

- In practice they aren't that difficult to use

- In regression we try to fit a multi-dimensional function to our data
- (You can use Gaussian Processes for classification, e.g. by inferring the probabilities of being in a class, but we ignore this as regression is where GP excel)
- In regression we have some p dimensional feature vectors $m{x}_i$ and some target $y_i \in \mathbb{R}$
- Our task is to fit a function through all the data points

- We can think of a solution as a function f(x)
- We can put a prior probability distribution, p(f), on a function, f, that prefers smooth functions
- We can then compute a posterior probability distribution on functions given the data, $p(f|\mathcal{D})$
- As a likelihood, $p(y_i|f(x_i))$, we use the probability of observing y_i given the true function value is $f(x_i)$
- In general, this would be next to impossible to compute

- In general, this would be next to impossible to compute, except in the special case where everything is Gaussian (normally) distributed

Outline

- 1. Introduction
- 2. Gaussian Processes
- 3. Bayesian Inference
- 4. Hyper-parameters

- Gaussian Processes are probability distributions over functions
- (Functions can be viewed as vectors in an infinite dimensional vector space)
- In the Gaussian Process, $\mathcal{GP}(m,k)$, the probability of a function, f, is proportional

$$p(f|m,k) \propto e^{-\frac{1}{2} \int (f(\boldsymbol{x}) - m(\boldsymbol{x})) k^{-1}(\boldsymbol{x},\boldsymbol{y}) (f(\boldsymbol{y}) - m(\boldsymbol{y})) d\boldsymbol{x} d\boldsymbol{y}}$$

- Gaussian Processes are probability distributions over functions
- (Functions can be viewed as vectors in an infinite dimensional vector space)
- In the Gaussian Process, $\mathcal{GP}(m,k)$, the probability of a function, f, is proportional

$$p(f|m,k) \propto e^{-\frac{1}{2} \int (f(\boldsymbol{x}) - m(\boldsymbol{x})) k^{-1}(\boldsymbol{x},\boldsymbol{y}) (f(\boldsymbol{y}) - m(\boldsymbol{y})) d\boldsymbol{x} d\boldsymbol{y}}$$

$$p(f|m,k) \propto e^{-\frac{1}{2} \int (f(\boldsymbol{x}) - m(\boldsymbol{x})) k^{-1}(\boldsymbol{x},\boldsymbol{y}) (f(\boldsymbol{y}) - m(\boldsymbol{y})) d\boldsymbol{x} d\boldsymbol{y}}$$

- Gaussian Processes are probability distributions over functions
- (Functions can be viewed as vectors in an infinite dimensional vector space)
- In the Gaussian Process, $\mathcal{GP}(m,k)$, the probability of a function, f, is proportional

$$p(f|m,k) \propto e^{-\frac{1}{2} \int (f(\boldsymbol{x}) - m(\boldsymbol{x})) k^{-1}(\boldsymbol{x},\boldsymbol{y}) (f(\boldsymbol{y}) - m(\boldsymbol{y})) d\boldsymbol{x} d\boldsymbol{y}}$$

Meaning of GP

- ullet To understand GP's we can discretise space, $oldsymbol{x}$, into a lattice of points $\{oldsymbol{x}_i\}$
- Then (assuming $m(\boldsymbol{x}) = 0$)

$$p(f|m,k) \propto \prod_{i} e^{-\frac{f_i^2 k^{-1}(\boldsymbol{x}_i,\boldsymbol{x}_i)}{2}} + f_i \sum_{j} k^{-1}(\boldsymbol{x}_i,\boldsymbol{x}_j) f_j$$

where $f_i = f(\boldsymbol{x}_i)$

 We see that the value of the function at each point is normally distributed with a mean that depends on functions at neighbouring points

Meaning of GP

- ullet To understand GP's we can discretise space, $oldsymbol{x}$, into a lattice of points $\{oldsymbol{x}_i\}$
- Then (assuming $m(\boldsymbol{x}) = 0$)

$$p(f|m,k) \propto \prod_{i} e^{-\frac{f_i^2 k^{-1}(\boldsymbol{x}_i,\boldsymbol{x}_i)}{2}} + f_i \sum_{j} k^{-1}(\boldsymbol{x}_i,\boldsymbol{x}_j) f_j$$

where $f_i = f(\boldsymbol{x}_i)$

 We see that the value of the function at each point is normally distributed with a mean that depends on functions at neighbouring points

Meaning of GP

- ullet To understand GP's we can discretise space, $oldsymbol{x}$, into a lattice of points $\{oldsymbol{x}_i\}$
- Then (assuming $m(\boldsymbol{x}) = 0$)

$$p(f|m,k) \propto \prod_{i} e^{-\frac{f_i^2 k^{-1}(\boldsymbol{x}_i,\boldsymbol{x}_i)}{2}} + f_i \sum_{j} k^{-1}(\boldsymbol{x}_i,\boldsymbol{x}_j) f_j$$

where $f_i = f(\boldsymbol{x}_i)$

 We see that the value of the function at each point is normally distributed with a mean that depends on functions at neighbouring points

$$\mathbb{E}\left[\left(f(\boldsymbol{x}) - m(\boldsymbol{x})\right)\left(f(\boldsymbol{y}) - m(\boldsymbol{y})\right)\right] = k(\boldsymbol{x}, \boldsymbol{y})$$

- This is sometimes know as a kernel—it must be positive semi-definite
- It is a free "parameter" that the user gets to choose (although we can learn its parameters too)
- If $k(\boldsymbol{x}, \boldsymbol{y})$ is a function of $\boldsymbol{x} \boldsymbol{y}$ it is "stationary"
- If $k(\boldsymbol{x}, \boldsymbol{y})$ is a function of $\|\boldsymbol{x} \boldsymbol{y}\|$ it is also "isometric"

$$\mathbb{E}\left[\left(f(\boldsymbol{x}) - m(\boldsymbol{x})\right)\left(f(\boldsymbol{y}) - m(\boldsymbol{y})\right)\right] = k(\boldsymbol{x}, \boldsymbol{y})$$

- This is sometimes know as a kernel—it must be positive semi-definite
- It is a free "parameter" that the user gets to choose (although we can learn its parameters too)
- If $k(\boldsymbol{x}, \boldsymbol{y})$ is a function of $\boldsymbol{x} \boldsymbol{y}$ it is "stationary"
- If $k(\boldsymbol{x}, \boldsymbol{y})$ is a function of $\|\boldsymbol{x} \boldsymbol{y}\|$ it is also "isometric"

$$\mathbb{E}\left[\left(f(\boldsymbol{x}) - m(\boldsymbol{x})\right)\left(f(\boldsymbol{y}) - m(\boldsymbol{y})\right)\right] = k(\boldsymbol{x}, \boldsymbol{y})$$

- This is sometimes know as a kernel—it must be positive semi-definite

- 3. Bayesian Inference
- 4. Hyper-parameters

• Given some data points $\mathcal{D} = ((\boldsymbol{x}_i, y_i) | i = 1, ..., m)$ the likelihood (assuming Gaussian error are independence of the data point) is given by

$$p(\mathcal{D}|f) = \prod_{i=1}^{m} \mathcal{N}(y_i | f(\boldsymbol{x}_i), \sigma^2)$$

- Using a Gausssian Process prior we can compute a posterior using Bayes's rule
- The posterior is a Gaussian Process with a shifted mean and variance depending on the data-points
- This direct Bayesian derivation gives the answer involving the inverse matrix of the correlation function, $k^{-1}(x,y)$

• Given some data points $\mathcal{D}=\left((\boldsymbol{x}_i,y_i)\big|i=1,...,m\right)$ the likelihood (assuming Gaussian error are independence of the data point) is given by

$$p(\mathcal{D}|f) = \prod_{i=1}^{m} \mathcal{N}(y_i | f(\boldsymbol{x}_i), \sigma^2)$$

Outline

- 1. Introduction
- 2. Gaussian Processes
- 3. Bayesian Inference
- 4. Hyper-parameters

- Choosing the correct covariance function is critical
- Most covariance functions include a continuous **hyper-parameter** (e.g. the correlation length ℓ) that we have to choose correctly
- This is typical of many Bayesian problems were we have some set of hyper-parameters, ϕ , describing the model
- These are different to the normal parameters we learn (e.g. weights ${\boldsymbol w}$ or in GP the functions $f({\boldsymbol x})$)
- In Bayesian inference we learn the posterior for these normal parameters

$$p(f|\mathcal{D}, \phi) = \frac{p(\mathcal{D}|f, \phi)p(f|\phi)}{p(\mathcal{D}|\phi)}$$

- Choosing the correct covariance function is critical

Choosing the Correct Covariance Function

- Choosing the correct covariance function is critical
- Most covariance functions include a continuous **hyper-parameter** (e.g. the correlation length ℓ) that we have to choose correctly
- This is typical of many Bayesian problems were we have some set of hyper-parameters, ϕ , describing the model
- These are different to the normal parameters we learn (e.g. weights ${\boldsymbol w}$ or in GP the functions $f({\boldsymbol x})$)
- In Bayesian inference we learn the posterior for these normal parameters

$$p(f|\mathcal{D}, \phi) = \frac{p(\mathcal{D}|f, \phi)p(f|\phi)}{p(\mathcal{D}|\phi)}$$

Evidence Framework

• The normalisation factor, $p(\mathcal{D}|\phi)$ is known as the **marginal** likelihood or evidence

$$p(\mathcal{D}|\boldsymbol{\phi}) = \int p(\mathcal{D}|f,\boldsymbol{\phi})p(f|\boldsymbol{\phi})df$$

ullet We can perform a Bayesian calculation at a second level by putting a prior on ϕ

$$p(\phi|\mathcal{D}) = \frac{p(\mathcal{D}|\phi)p(\phi)}{p(\mathcal{D})}$$

From this we can now marginalise out the hyper-parameters

$$p(f|\mathcal{D}) = \int p(f|\mathcal{D}, \boldsymbol{\phi}) p(\boldsymbol{\phi}|\mathcal{D}) d\boldsymbol{\phi}$$

Evidence Framework

• The normalisation factor, $p(\mathcal{D}|\phi)$ is known as the **marginal** likelihood or evidence

$$p(\mathcal{D}|\boldsymbol{\phi}) = \int p(\mathcal{D}|f,\boldsymbol{\phi})p(f|\boldsymbol{\phi})df$$

ullet We can perform a Bayesian calculation at a second level by putting a prior on ϕ

$$p(\boldsymbol{\phi}|\mathcal{D}) = \frac{p(\mathcal{D}|\boldsymbol{\phi})p(\boldsymbol{\phi})}{p(\mathcal{D})}$$

From this we can now marginalise out the hyper-parameters

$$p(f|\mathcal{D}) = \int p(f|\mathcal{D}, \boldsymbol{\phi}) p(\boldsymbol{\phi}|\mathcal{D}) d\boldsymbol{\phi}$$

Evidence Framework

• The normalisation factor, $p(\mathcal{D}|\phi)$ is known as the **marginal** likelihood or evidence

$$p(\mathcal{D}|\boldsymbol{\phi}) = \int p(\mathcal{D}|f,\boldsymbol{\phi})p(f|\boldsymbol{\phi})df$$

ullet We can perform a Bayesian calculation at a second level by putting a prior on ϕ

$$p(\phi|\mathcal{D}) = \frac{p(\mathcal{D}|\phi)p(\phi)}{p(\mathcal{D})}$$

From this we can now marginalise out the hyper-parameters

$$p(f|\mathcal{D}) = \int p(f|\mathcal{D}, \boldsymbol{\phi}) p(\boldsymbol{\phi}|\mathcal{D}) d\boldsymbol{\phi}$$

The integral

$$p(f|\mathcal{D}) = \int p(f|\mathcal{D}, \phi) p(\phi|\mathcal{D}) d\phi$$

- An alternative is to use the most likely hyper-parameter
- ullet We can find this by using gradient search of $p(\mathcal{D}|oldsymbol{\phi})$
- This is sometimes referred to as ML-II
- Normally even this can be difficult, but for GP its not too difficult

The integral

$$p(f|\mathcal{D}) = \int p(f|\mathcal{D}, \boldsymbol{\phi}) p(\boldsymbol{\phi}|\mathcal{D}) d\boldsymbol{\phi}$$

- * First term measures goodness of fit
- ⋆ Second term measure complexity of model
- ★ Last term is a common normalisation constant
- Can efficiently compute derivatives and find best parameters

$$\log(p(\mathcal{D}|\boldsymbol{\phi})) = -\frac{1}{2}\boldsymbol{y}^\mathsf{T}(\mathbf{K} + \sigma^2\mathbf{I})\boldsymbol{y} - \frac{1}{2}\log(|\mathbf{K} + \sigma^2\mathbf{I}|) - \frac{m}{2}\log(2\pi)$$

- * First term measures goodness of fit
- ⋆ Second term measure complexity of model
- ★ Last term is a common normalisation constant
- Can efficiently compute derivatives and find best parameters
- Could overfit!

Example (slightly pathological)

- Gaussian processes are very powerful for regression (and classification?)
- Because all calculations involve Gaussian integrals we can compute everything in closed form
- (Actually its a pain to do the mathematics because you end up working with inverse of matrices)
- Fairly generic (black-box) technique because the prior captures many continuity constraints
- We can use the evidence framework (probability of data) to do model selection and hyper-parameter optimisations
