Communicating Via a Noisy Channel

• Information theory considers communicating down a (noisy) channel

$$X \sim \mathbb{P}(X) \xrightarrow{\text{noisy channel}} Y \sim \mathbb{P}(Y \mid X)$$

- We send a message X (with probability $\mathbb{P}(X)$) and receive a message Y with probability $\mathbb{P}(Y \mid X)$
- \bullet The uncertainty of the message sent, given we received a message y is

$$H_{X\mid Y=y} = -\sum_{x\in\mathcal{X}} \mathbb{P}(X=x\mid Y=y) \log(\mathbb{P}(X=x\mid Y=y)) \blacksquare$$

• The expected uncertainty in the message sent is

$$H_{X|Y} = \sum_{y \in \mathcal{Y}} \mathbb{P}(Y = y) H_{X|Y=y} = -\sum_{x,y} \mathbb{P}(X = x, Y = y) \log(\mathbb{P}(X = x \mid Y = y))$$

- 1. Information Theory
- 2. KL-Divergence
- 3. Minimum Description Length
- 4. Variational **Auto-Encoders**

 $H_{X,Y}$ H_X $H_{X|Y}$ $H_{Y|X}$ $I_{X:Y} = I_{Y:X}$

Joint Entropy

• We can define the joint entropy

$$H_{X,Y} = -\sum_{x,y} P_{X,Y}(x,y) \log(P_{X,Y}(x,y))$$

- If the message we receive is independent of the message that is sent then $H_{X,Y} = H_X + H_Y$ (we saw this in the last lecture)
- $H_{XY} \neq H_X + H_Y$ if X and Y are correlated
- Since $\mathbb{P}(X,Y) = \mathbb{P}(Y|X)\mathbb{P}(X) = \mathbb{P}(X|Y)\mathbb{P}(Y)$ if follows

$$H_{X,Y} = H_X + H_{Y|X} = H_Y + H_{X|Y}$$

• Or $H_X - H_{X|Y} = H_Y - H_{Y|X}$

Mutual Information

- The amount of uncertainty about the message being sent, X, before receiving the message is $H_X = -\mathbb{E}_X[\log \mathbb{P}(X)]$
- Shannon define the *mutual information* to be the expected loss in uncertainty when we receive a message

$$I_{X;Y} = H_X - H_{X|Y}$$

• Since $H_X - H_{X|Y} = H_Y - H_{Y|X}$ it follows

$$I_{X;Y} = I_{Y;X}$$

https://ecs-vlc.github.io/comp6208/

Independent Noise

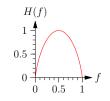

• The simplest model of a noisy channel is a binary channel where each symbol is corrupted independently with a probability *f*

$$\mathbb{P}(X = 1 | Y = 0) = \mathbb{P}(X = 0 | Y = 1) = f$$

• An elementary calculations shows that

$$H_{X_i|Y_i} = -(1-f)\log(1-f) - f\log(f) = H(f)$$

ullet For a message of length n, $H_{X|Y}=nH(f)$

Channel Capacity

• We can summarise these relationships diagrammatically

| $H_{X,Y}$ | | | |
|-----------|---------------------|-----------|--|
| H_X | | | |
| H_Y | | | |
| $H_{X Y}$ | $I_{X;Y} = I_{Y;X}$ | $H_{Y X}$ | |

• Shannon defined the *capacity* of a noisy channel as

$$C = \max_{\mathbb{P}(X)} I_{X;Y}$$

 That is, you choose the probability distribution of the message to maximise the information gain!

COMP6208 Advanced Machine Learning

https://ecs-vlc.github.io/comp6208/

Error Correcting Codes

- To reduce the chance of misinterpreting a message we need to build an error correcting code!
- We can do this dividing the space of binary messages into a set of Hamming balls

• A Hamming ball B(x,r) is the set of strings that differ from n-dimensional binary string, x, by at most r digits

Volume of Coding Space

- ullet The expected number of errors in a string of length n given an error rate of f is nf
- For sufficiently large n we would expect all errors are smaller than $(f+\epsilon)n$ (for $\epsilon>0$)
- If we make the radius of the Hamming ball $r = (f + \epsilon)n$ ($\epsilon > 0$) then we would expect no error for sufficiently large n!
- ullet An upper bound on the number of code words we can send in a string of length n is

$$\frac{2^n}{|B(\boldsymbol{x}_i,r)|} = c\sqrt{n}2^{I_{X;Y}}$$

https://ecs-vlc.github.io/comp6208/

Using Mutual Information

- Mutual information is used quite often in machine learning
 - ★ Wikipedia mentions 14 applications
- Suppose we want to align two sets of images through some non-linear transformations
- One way of doing this is to choose the non-linear transformations that maximise the mutual information (or normalised mutual information) between the two sets of images

Lower Bounds

- Shannon also showed that choosing $2^{I_{X;Y}}$ random strings of length n the Hamming distance beween balls would be at least f with high probability!
- This means that we can send information at rate of $I_{X:Y}$
- ullet The maximum rate is given by the channel capacity $\max I_{X;Y}$
- If f=0.1 then $C=I_{X;Y}=0.469\,\mathrm{bits}$ so we need codes of just over twice as long to communicate accurately over a noisy channel with a 10% corruption rate.
- Unfortunately, we can't efficiently decode random code positions, so although we know Shannon's bound is achievable we don't have practical codes that do this!

Outline

- 1. Information Theory
- 2. KL-Divergence
- 3. Minimum Description Length
- 4. Variational Auto-Encoders

KL-Divergence

• We have met the Kullback-Leibler divergence

$$KL(p||q) = \mathbb{E}_{X \sim p(X)} \left[\log \left(\frac{p(X)}{q(X)} \right) \right]$$
$$= -\mathbb{E}_{X \sim p(X)} [\log(q(X))] - H_X$$

- Recall $-\log(q(X=x))$ is the length of code need to send a message x with a probability q(X = x)
- Thus $-\mathbb{E}_{X \sim p(X)}[\log(q(X))]$ is the expected length of message needed to code $X \sim p(X)$ using the optimal code for the distribution q(X) that than p(X)
- KL(p||q) is also known as the **relative entropy** and measures the expected extra length in coding $X \sim p(X)$ if we use the wrong distribution q(X)

Evidence Lower Bound (ELBO)

• We can re-write the variational free energy as

$$\begin{split} \Phi(\phi) &= -\int g(\boldsymbol{\theta} \mid \phi) \log \left(\frac{g(\boldsymbol{\theta} \mid \phi)}{(f(\boldsymbol{\theta}, \mathcal{D}) / f(\mathcal{D})) f(\mathcal{D})} \right) \mathrm{d}\boldsymbol{\theta} \\ &= -\int g(\boldsymbol{\theta} \mid \phi) \left(\log \left(\frac{g(\boldsymbol{\theta} \mid \phi)}{f(\boldsymbol{\theta} \mid \mathcal{D})} \right) - \log(f(\mathcal{D})) \right) \mathrm{d}\boldsymbol{\theta} \\ &= -\mathrm{KL} \left(g(\boldsymbol{\theta} \mid \phi) \middle\| f(\boldsymbol{\theta} \mid \mathcal{D}) \right) + \log(f(\mathcal{D})) \end{split}$$

- If we maximise $\Phi(\phi)$, we end up minimising the KL divergence between q and f so that $q \approx f$ and $\Phi(\phi) \approx \log(f(D))$
- That is, we choose the parameters of our simple factorised distribution so that it is close to the true posterior

Variational Approximation

- Recall we use MCMC in Bayesian inference because the posterior distribution is too complicated to write down in closed form
- In the variational approximation we approximate the posterior distribution by a simpler (typically factored distribution), e.g.

$$f(\boldsymbol{\theta} \mid \mathcal{D}) \approx g(\boldsymbol{\theta} \mid \boldsymbol{\phi}) = \prod_{i} g(\theta_i \mid \phi_i)$$

• The standard method for solving this is to maximise the variational free energy

$$\Phi(\phi) = -\int g(\theta \mid \phi) \log \left(\frac{g(\theta \mid \phi)}{f(\theta, \mathcal{D})} \right) d\theta$$

Put Another Way

• We can rewrite the variational free energy as $\Phi(\phi) = L_a(\phi) + H_a(\phi)$ where

$$L_q(\phi) = \int g(\theta \mid \phi) \left(\log(f(\mathcal{D}|\theta)) + \log(f(\theta)) \right) d\phi$$

acts like an expected posterior term that is maximised when the data is well modelled (we put the probability density, $q(\theta \mid \phi)$ where the $f(\boldsymbol{\theta}, \mathcal{D})$ is large)

• The second term is an entropy

$$H_q(\phi) = -\int g(\theta \mid \phi) \log(g(\theta \mid \phi)) d\phi$$

That is, we maximise the uncertainty of the distribution $g(\theta \mid \phi)$

Using Variational Methods

- Variational methods can be much faster than MCMC (although they tend to involve some iterations to minimise the variation free energy)
- The can produce very good approximations, although this is not guaranteed (depends on the problem)
- They can be extended (e.g. by minimising $\mathrm{KL}(g\|f)$ rather than $\mathrm{KL}(f\|g)$ —this is known as $\mathit{belief\ propagation})$.
- MCMC is less elegant, but is a controlled approximation (we get better results by increasing the number of iterations)
- MCMC is slower, but on modern computers this isn't usually a problem!

Compression and Model Selection

- Outside of the Bayesian framework it is difficult to do model selection—most of ML isn't Bayesian.
- When is it better to accept a more complex model for a better fit and when are we just over-fitting?
- Usually we answer this using a validation set, but this is not always possible
- One principled approach is to use the model that allows us to maximally compress the data
- If we are compressing the data then we are capturing features of the data

Outline

- 1. Information Theory
- 2. KL-Divergence
- 3. Minimum Description Length
- 4. Variational Auto-Encoders

| $H_{X,Y}$ | | | |
|-----------|---------------------|-----------|--|
| H_X | | | |
| | H_Y | | |
| $H_{X Y}$ | $I_{X;Y} = I_{Y;X}$ | $H_{Y X}$ | |

Alice and Bob

- Suppose Alice has data $\mathcal{D}=\{(\boldsymbol{x}_i,y_i)\mid i=1,2,...,m\}$ while Bob has only the feature vectors $\{\boldsymbol{x}_i\mid i=1,2,...,m\}$
- Alice wants to communicate y_i to Bob as efficiently as possible
- ullet We suppose Alice & Bob have available a model $\hat{f}(oldsymbol{x}|oldsymbol{ heta})$
- Rather than sending the complete list $\{y_i \mid i=1,2,...,m\}$ Alice can send Bob the parameter θ and the errors

$$\delta_i = y_i - \hat{f}(\boldsymbol{x}_i|\boldsymbol{\theta})$$

• Assuming the δ_i 's have a distribution p_δ then the cost of communicating an error to accuracy Δ is $-\log(p_\delta(\delta_i) \times \Delta)$

Description Length

• The **description length** for $\{y_i \mid i=1,2,...,m\}$ is then the cost of transmitting θ plus the cost of transmitting the errors

$$L = \sum_{k=1}^{n} \ell(\theta_k) - \sum_{i=1}^{m} \left(\log \left(p_{\delta} \left(y_i - \hat{f}(\boldsymbol{x}_i | \boldsymbol{\theta}) \right) \right) + \log(\Delta) \right)$$

where $\ell(\theta_k)$ is the number of bits need to communicate θ_k (we get to choose the accuracy if is worth encoding the parameters)

- To select between models we choose the model with the minimum description length
- Note that the accuracy Δ will lead to the same cost, $-m\log(\Delta)$, for all models so doesn't affect which model is selected

Outline

- 1. Information Theory
- 2. KL-Divergence
- 3. Minimum Description Length
- 4. Variational **Auto-Encoders**

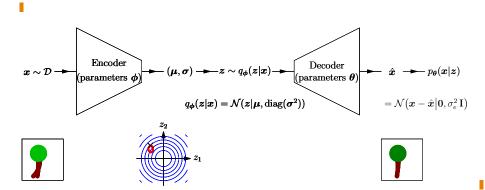

Minimum Description Length (MDL) Method

- The minimum description length method can be a powerful way of choosing between models
- Often it is the only principled method available
- It allows you to trade model accuracy against model complexity
- It can be fiddly as we need to determine the accuracy to which we should store the parameters of our model
- This isn't something we usually think about, but often we can get very good models even when we truncate the parameters to low precision

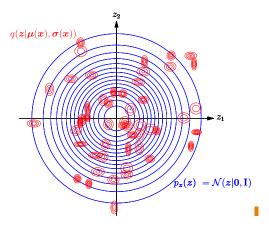

Adam Prügel-Bennett

Variational Auto-Encoders VAE

$$\mathcal{L} = \mathbb{E}_{oldsymbol{x} \sim \mathcal{D}} ig[\mathrm{KL} ig(q_{oldsymbol{ heta}}(oldsymbol{z} | oldsymbol{x}) ig\| \mathcal{N}(oldsymbol{0}, \mathbf{I}) ig) - \log(p_{oldsymbol{ heta}}(oldsymbol{x} | oldsymbol{z}(oldsymbol{x})) ig]$$

Latent Space

$$\mathrm{KL}\big(q_{\boldsymbol{\theta}}(\boldsymbol{z}|\boldsymbol{x})\big\|\mathcal{N}(\boldsymbol{0},\mathbf{I})\big) \mathbf{I}$$

Adam Prügel-Bennett

COMP6208 Advanced Machine Learning

https://ecs-vlc.github.io/comp6208/

Adam Prügel-Bennett

COMP6208 Advanced Machine Learning

https://ecs-vlc.github.io/comp6208/

Description Length

The loss

$$\mathcal{L} = \mathbb{E}_{\boldsymbol{x} \sim \mathcal{D}} \left[\text{KL} \left(q_{\boldsymbol{\theta}}(\boldsymbol{z} | \boldsymbol{x}) \middle\| \mathcal{N}(\boldsymbol{0}, \mathbf{I}) \right) - \log(p_{\boldsymbol{\theta}}(\boldsymbol{x} | \boldsymbol{z}(\boldsymbol{x}))) \right]$$

can be interpreted as

- \star The cost of communicating the code $\mathrm{KL}ig(q_{m{ heta}}(m{z}|m{x})\|\mathcal{N}(\mathbf{0},\mathbf{I})ig)$
- \star Plus the cost to send the repair $\log(p_{m{ heta}}(m{x}|m{z}(m{x})))$
- We minimise the loss function equivalent to MDL
- What is really clever is that we can choose the accuracy of the code we send $q_{\theta}(z|x)$ to minimise the over-all cost

Understanding the Loss Function

- The original paper derived the loss function as a variational approximation to maximising some posterior
- This is difficult to understand (at least, for me)
- It has a very natural explanation in terms of minimum description length
- Alice wants to communicate the images to Bob
- Alice uses the encoder to derive a (latent) code $q(\boldsymbol{z}|\boldsymbol{x})$ which she communicates to Bob
- ullet She also communicates the errors $oldsymbol{\delta} = x ar{x}$
- ullet Bob uses the decoder to decode $q(oldsymbol{z}|oldsymbol{x})$ and $oldsymbol{\delta}$ to repair the images

Conclusions

- Information theory has regularly been used in machine learning
- It requires some understanding and care to do it properly
- The KL-divergence (or relative entropy) is often used to make two probability distribution more alike!
- The minimum description length is a powerful principle for model selection
- Variational Auto-Encoders have a very natural interpretation in terms of minimising a description length
